Computational Graph for GNNs

Computational graph for node **i** corresponding to a 2-layer GNN

Image Source: [Lin et al., 2021]

At inference time decision of a GNN on a particular node can be attributed to important nodes/edges and their features in its computational graph.

Explainable GraphML

Supervised GNNS

Why was a node/edge/graph assigned a particular label?

Decision has to be explained not only in terms of features but also graph structure. General explainability methods cannot be trivially applied for graphs.

When features are themselves uninterpretable?

<u>Unsupervised node embeddings</u>

What do node embeddings encode?

No task information. Need to decode/explain embeddings in terms of input graph structure. **What should an explanation look like?**

# Post hoc explanations Vs. Self explaining models

Post-hoc explanations

Self explaining models

Explaining an already trained complex model
does not affect its performance

Explanations might not be faithful to the model

There is usually a tradeoff between interpretability and performance

Explanations are by design faithful to the model

Local Vs Global Explanation

Vs.

Local or instance level explanations for explaining Individual predictions

Global explanations should ideally should explain complete model behaviour

Key Challenges

How to **define** explanations?

       Uncover effect of various input elements in decision making

       User of the explanation should be able to understand the explanation

How to **evaluate** the **explainer** and the **explanations**?

       Agreement with the decision logic of the model

       Should be human understandable

Post-hoc explanations for supervised GNNs

Substructure and feature importances

Substructures and subset of input features

Substructure and feature importances

Substructures and subset of input features

Counterfactuals

Smallest amount of perturbation on the input graph which result in change in GNN's prediction

Recourse rules for improving molecules to combat HIV (Image adapted from Huang et al., 2023)

Counterfactuals

Smallest amount of perturbation on the input graph which result in change in GNN's prediction

Recourse rules for improving molecules to combat HIV (Image adapted from Huang et al., 2023)

Concepts

Concepts are small higher level units of information that can be interpreted by humans

Examples : motifs in graphs or specific properties like "node degree > 6" or "node next to carbon atom"

Image source: Azzolin et al., 2023

Concepts

Concepts are small higher level units of information that can be interpreted by humans

Examples : motifs in graphs or carbon atom"

19

Substructure and feature explanations

Valid Explanation

A **subset** of the input such that the prediction while just using the input stays the same as the original prediction is a **valid** explanation

Sparsity

But a complete input is also a valid explanation

The chosen subset (explanation) should be sparse

Stability

What happens to the not selected part of the input?

$$\xrightarrow[\Phi]{GNN} \quad \mathbb{E} \quad 1$$

- Set the not selected part by some noisy values.

- Check the expected prediction over multiple such perturbations.

A stable explanation is one which achieves in expectation a close prediction to that of the original prediction

Constructing a perturbed input

Selected nodes and features are marked green

Construct a perturbed input by setting selected features of selected nodes (the **green** cells) to their true values and others to random noisy values

If **M**(S) corresponds to product of feature and node masks, we obtain the perturbed input as

$$\mathbf{X}_S = \mathbf{X} \odot \mathbf{M}(S) + \mathbf{Z} \odot (\mathbf{1} - \mathbf{M}(S)), \mathbf{Z}_{ij} \sim \mathcal{N}$$

RDT-Fidelity of an explanation

Computation Graph for node n

$$F(S) = \mathbb{E}_{\mathbf{X}_S | Z \sim \mathcal{N}} \left[\mathbf{1}_{\Phi(\mathbf{X}) = \Phi(\mathbf{X}_S)} \right]$$

with

$$\mathbf{X}_S = \mathbf{X} \odot \mathbf{M}(S) + \mathbf{Z} \odot (\mathbf{1} - \mathbf{M}(S)), \mathbf{Z}_{ij} \sim \mathcal{N}$$

Zorro
Find the sparsest explanation such that its RDT-fidelity is maximised.

Evaluating Post-Hoc Explanations

Evaluating Post-Hoc Explanations

Evaluating the explainer

Evaluating the explanation

Faithfullness

↓

Sparsity

Correctness
(Right for right
reasons)

Plausibility

[BAGEL Benchmark, Rathee et al. 2022]

https://github.com/Mandeep-Rathee/Bagel-benchmark

Faithfullness

Take 1: Check *sufficiency* and *comprehensiveness* of the explanation

Sufficiency

Keep the most important features/nodes/edges and check if they alone can predict the original decision.

Comprehensiveness

Remove the features/nodes/edges not in the explanation and check if the original prediction changes.

Faithfullness

How to compute sufficiency and comprehensiveness for soft masks?

What happens when you cannot remove features?

Take 2: Use RDT-Fidelity to check if the explanation is predictive and stable

$$F(S) = \mathbb{E}_{\mathbf{X}_S | Z \sim \mathcal{N}} \left[\mathbf{1}_{\Phi(\mathbf{X}) = \Phi(\mathbf{X}_S)} \right]$$

Where

$$\mathbf{X}_S = \mathbf{X} \odot \mathbf{M}(S) + \mathbf{Z} \odot (\mathbf{1} - \mathbf{M}(S)), \mathbf{Z}_{ij} \sim \mathcal{N}$$

Sparsity

But the full input is also a faithful explanation

Are the explanations non-trivial?

Take 1: Spars... = Selection size / total

$$\Phi$$

$$\Phi$$

Sparsity

What about soft masks ?

A uniform distribution of normalised mask distribution implies complete input

Take 2: Check Entropy of normalised distribution of masks

Lower the entropy sparser the explanation

Correctness

Can the explainer detect any injected correlations responsible for altering model's behavior ?

Introduce **correlations** in the training data which can change the decision on a node/graph. Then check if explanation discovers the added correlations.

Target Node

Incorrect prediction

CAM

The first problem that fair game has is the casting of supermodel cindy crawford in the lead role. not that cindy does that bad... sure william is n't a bad actor. unfortunately he just does n't demonstrate it all in this movie...

Compute agreement of explanation with human rationales

Metrics : F1 score for hard masks, AUPRC score for soft masks

Plausibility

Should be used in conjunction with a suitable faithfulness metric

First ensure that the explanation is in fact approximating model's decision

GCN

The first problem that fair game has is the casting of supermodel cindy crawford in the lead role. not that cindy does that bad... sure william is n't a bad actor. unfortunately he just does n't demonstrate it all in this movie...

GAT

The first problem that fair game has is the casting of supermodel cindy crawford in the lead role. not that cindy does that bad... sure william is n't a bad actor. unfortunately he just does n't demonstrate it all in this movie...

APPNP

The first problem that fair game has is the casting of supermodel cindy crawford in the lead role. not that cindy does that bad... sure william is n't a bad actor. unfortunately he just does n't demonstrate it all in this movie...

Given the explainer is faithful to the model one can use plausibility to compare GNN models for the agreement of their decision making process with human rationales.

Other Evaluation schemes

Measuring agreement (explanation accuracy) with planted subgraph in a synthetic graph

Image Source : GNNExplainer

Drawback/Issue : How to be sure if the model picked the planted subgraph?

Other Evaluation schemes

Measuring attribution (explanation) consistency across high performing models

[Sanchez-Lengeling et al. 2020]

Consistency

Quantifies the variability in explanation accuracy using the top 10% of models through a hyperparameter scan over model architectures

Drawback/Issue : How to be sure if the models used the intended explanation?

Explaining Node Embeddings

Global explanations for embedding dimensions

$$e : \mathcal{G} \to \mathbb{R}^D$$
